**Summary.** *Myxobolus testicularis* sp. n. was found within cyst-like structures in the testis of the freshwater fish *Hemiodopsis microlepis* Kner, 1859 (Teleostei, Hemiodontidae) in close contact with the testis stroma. The fish were collected in the Poty River, near the city of Teresina (State of Piauí, Brazil). Large spherical to ellipsoidal plasmodia up to 0.5 mm were filled with disporic pansporoblasts and mature spores. The plasmodial wall presented a sinuous outline surrounded by several fibroblasts and a continuous layer of numerous collagen fibrils. The plasmodia contained different proliferative stages. Early sporogenic cells were present in the cortical zone. Immature and mature spores were located more internally. Ellipsoidal spores measured 8.6 ± 0.5 µm (n = 30) length, 7.2 ± 0.5 µm (n = 15) width, and 2.7 ± 0.4 µm (n = 12) thickness. The anterior end of the spores contained two equal pyriform polar capsules measuring 3.5 ± 0.3 µm (n = 15) length, 1.7 ± 0.4 µm (n = 10) width, each with an isofilar polar filament with 5-6 turns obliquely to the longitudinal axis. The wall of the polar capsule was filled with a hyaline substance contrasting with the very dense internal matrix. The spores consisted of two equal valves forming the wall. The spore wall was surrounded by a dense and uniform layer with variable thickness (up to 0.6 µm) consisting of a complicated network of anastomosed microfibrils closely adhered to the wall. More externally, in the plasmodial matrix, the fibrils formed a looser network. Based on the ultrastructural morphology and specificity to the host species, we propose the creation of a new species, named *Myxobolus testicularis* sp. n.

**Key words:** fish parasite, *Myxobolus testicularis* sp. n., Myxozoa, ultrastructure.

**INTRODUCTION**

Numerous descriptions of myxosporeans have been reported in fish from different geographic areas (Landsberg and Lom 1991, Lom and Dyková 1992). Myxozoa Bütschli, 1882 comprises more than 1200 available species commonly found in fish (Lom and Dyková 1992). Among them, the genus *Myxobolus* Bütschli, 1882, with 744 species described, is the largest group of the Myxobolidae family (Eiras et al. 2005), and has been reported as an important pathogen in freshwater fishes (Kent et al. 2001).

Although considerable information has already been collected on South America myxozoans, the available descriptions are based, almost exclusively, on light microscopical records and diagrammatic drawings of the spores (Aragão 1919, Nemeczek 1926, Penido 1927,
Pinto 1928, Walliker 1969, Kent and Hoffman 1984, Molnár and Békési 1993, Cellere et al. 2002). At the present, nineteen Brazilian Myxobolus species have been described from different host fishes (Walliker 1969; Kent and Hoffman 1984; Molnár and Békési 1993; Gioia and Cordeiro 1996; Casal et al. 1996, 2002; Molnár et al. 1998; Adriano et al. 2002; Azevedo et al. 2002). However, very few represent ultrastructural studies on Myxobolus sp. from Brazil, of which only three species have been described (Casal et al. 1996, 2002; Azevedo et al. 2002).

The present study gives ultrastructural details of the developmental stages, including spores of a new myxosporean infecting the Amazonian teleost Hemiodopsis microlepis Kner, 1859 species. The morphological characteristics and taxonomic position of the new species are discussed.

MATERIALS AND METHODS

Forty specimens (27 males and 13 females) of Hemiodopsis microlepis Kner, 1859 (Teleostei: Hemiodontidae) known by the Brazilian common name “Flexeiro”; were collected from Poty River (05º05’21”S/ 42º48’07”W), near the city of Teresina (State of Piauí), NE Brazil. The fishes were killed by over-anaesthetising in MS 222 (3-aminobenzoic acid ethyl ester) (Sandoz Laboratories) and dissected. Small fresh fragments of testes, ovary, gills, kidney and liver were excised and examined under light microscope with Nomarski differential interference contrast (DIC) optics. The infected testes were observed by DIC for spore measurement. For ultrastructural studies, small fragments of infected tissues were excised and fixed in 2% OsO₄ buffered with the same solution for 4 h at the same temperature. After dehydration in a graded ethanol-series followed by two changes of propylene oxide (4 h in each), samples were embedded in Epon. Semithin sections were cut with a diamond knife, anastomosed microfibrils closely adhered to the wall (Figs 5-8). More externally, these microfibrils formed a more diffused network (Fig. 5). The layer of microfibrils was absent in early sporogenic cells. It appeared during the spore maturation stage and attained maximum development in the mature spore (Fig. 4). A schematic drawing of the ultrastructure of the spore (Fig. 9) was made from serial ultrathin sections and another was obtained by DIC observations (Fig. 10).

**Myxobolus testicularis sp. n. (Figs 1-10)**

- **Type host:** Hemiodopsis microlepis Kner, 1859 (Teleostei: Hemiodontidae) (Brazilian common name “flexeiro”).
- **Site of infection:** Plasmodium in contact with the seminiferous lumen.
- **Prevalence of infection:** Seven of 40 (17.5 %) of the total fish or 7 of 27 (25.9 %) male fish were parasitized.
- **Type locality:** Poty River near the city of Teresina (State of Piauí), NE Brazil (Latitude: 05º05’21”S; Longitude: 42º48’07”W).

**Description of spores:** The spores were typical of the genus Myxobolus Bütschli, 1882 because they were rounded in valvular view and biconvex in sutural view, and the shell valves were smooth and without projections. They measured 8.2-9.1 (8.6 ± 0.5) µm (n = 30) in length, 6.7-7.5 (7.2 ± 0.5) µm (n = 15) in width and 2.4-3.0 (2.7 ± 0.4) µm (n = 12) in thickness (Fig. 1 insert, 5-7). The spores consisted of two equal dense valves adhering together along the suture line forming the wall (Figs 5-8). Two equal smooth polar capsules, located symmetrically to the spore axis, measured about 3.3-3.8 (3.5 ± 0.3) (n = 15) × 1.3-2.0 (1.7 ± 0.4) (n = 10) µm each and contained a polar filament with 5-6 turns in a single layer surrounded by a dense matrix (Figs 6, 7). Sporoplasm containing two nuclei was surrounded by irregular patches of dense matter (Fig. 5). The spore wall was smooth and contained a dense and uniform layer with variable thickness (up to 2 µm) of numerous anastomosed microfibrils closely adhered to the wall (Figs 5-8). More externally, these microfibrils formed a more diffused network (Fig. 5). The layer of microfibrils was absent in early sporogenic cells. It appeared during the spore maturation stage and attained maximum development in the mature spore (Fig. 4). A schematic drawing of the ultrastructure of the spore (Fig. 9) was made from serial ultrathin sections and another was obtained by DIC observations (Fig. 10).

**Type specimens:** One slide with paratypes and one slide with semithin sections of the cyst containing spores and surrounding tissues were deposited in the Interna-
Figs 1-3. *Myxobolus testicularis* sp. n. 1 - semithin section of a cyst-like structure, showing numerous spores; 1 insert - some free mature spores released from the cyst-like structure observed in DIC optics; 2 - semithin section of the periphery of the cyst-like structure, showing some spermatozoa (Sz) in close contact with the wall. Near the periphery of the plasmodium some early sporogenic cells (*) are present; 3 - ultrathin section of the periphery of the cyst-like structure showing different life cycle stages (\* - young sporogenic stages, iS - immature spores). In the wall, one fibroblast (F) and numerous collagen fibres (arrowheads) are present.
Etymology: The specific epithet “testicularis” derives from the name of the infected organ of the host.

DISCUSSION

The light and ultrastructural morphology of the spores described in the present work, corresponds to those of genus *Myxobolus* (family *Myxobolidae*) (Lom and Noble 1984, Lom and Dyková 1992).

When comparing these results with those obtained for the different *Myxobolus* spp., with equal polar capsules, previously described mainly from Brazilian host fishes (Table 1), both *Myxobolus kudoi* Guimarães et Bergamin, 1938 and *Myxobolus lutzi* Aragão, 1919 show similarities with our results. The spores of *M. kudoi* and its polar capsules have very similar dimensions to those of *M. testicularis* sp. n. (Table 1). Despite the fact that the only information available on *M. kudoi* represents diagrammatic drawings of the spores, the morphology seems quite dissimilar from that of *M. testicularis* sp. n. In *M. kudoi*, the spores appear to be pyriform shaped, while in *M. testicularis* sp. n. they are almost circular with small differences in the length and width diameters. It is particularly difficult to establish a comparison between the spores of *M. testicularis* sp. n. and *M. lutzi* because the only data available on the later is the medium length and the width of the spore (Table 1) and a diagrammatic drawing. In spite of their similar spore dimensions, a close analysis of the diagrammatic drawing of *M. lutzi* reveals that is clearly pyriform shaped unlike *M. testicularis* sp. n., which is rounder.

*Myxobolus* sp. are very common parasites of freshwater fishes. In most of the fishes studied, one or more *Myxobolus* species were found. Although there have been very few studies on the host specificity of *Myxobolus* sp., new data indicates that most species are strictly host specific or only capable of developing in closely related fishes (Molnár et al. 1998). These studies support the distinction between *M. testicularis* sp. n. that appears in the testes of *Hemiodopsis microlepis* (Teleostei: Hemidontidae), *M. kudoi* which parasitizes the body skin except the fins of “Nematognatha” sp.”
Table 1. Characters and dimensions (in µm) of the spores and the polar capsules in species of *Myxobolus* found in Brazil which show only one type of spore and equal polar capsules.

*Present study*
Figs 5-8. *Myxobolus testicularis* sp. n. 5 - ultrathin section of some spores sectioned at different levels, showing the spore organization with special emphasis on the surrounding microfibrils (arrows). More externally, a loose network of anastomosed microfibrils (arrowheads) is seen. In the spore section located below, two nucleus (N) are observed in the sporoplasm; 6 - ultrathin longitudinal section of a spore in frontal view (slightly oblique), showing all spore elements arrows - surrounding microfibrils, V - valves, PC - polar capsules each with a coiled polar tube (arrowheads), Sp - sporoplasm, N - nucleus; 7 - ultrathin transverse section at the polar capsules (PC) level, showing their circular transverse section, the equal valves (V) and the surrounding microfibrils (arrows); 8 - ultrastructural detail of the two equal valves (V), the sutural line (arrowheads) and the complex network of anastomosed microfibrils (arrows).
Myxobolus testicularis sp. n., parasite of fish (Pisces) (Guimarães and Bergamin 1938), and M. lutzi which appears in the testes of Poecilia vivipara (Teleost). The British Museum (Natural History) considers that “Nematognatha sp.” probably refers to catfish.

Our results show several morphological differences between M. testicularis sp. n. and other Myxobolus spp. described from South America mainly in the dimension and shape of the spores and polar capsules, as well as in the number, position and structure of the coils in the polar filament. Moreover, another difference between the present species and those previously described, is in the complicated network of irregular and anastomosed surrounding microfibrils forming projections in the spore wall towards the periphery of the spore. This feature has never been observed before in other Myxobolus sp. from South America. Nevertheless, in Henneuguya pilosa the spores present similar fibrils to our results (Azevedo and Matos 2003). These fibrils were only observed by TEM and not by DIC because they were not distinguishable from the spore wall.

Based on these differences, and host specificity we are able to justify the establishment of a new species, named *Myxobolus testicularis* sp. n.

**Acknowledgments.** This study was partially supported by Eng. A. Almeida Foundation, Porto, Portugal. We would like to thank Mr. João Carvalheiro for the excellent technical assistance, and Gerson Rodrigues for collecting the fishes.
